

Funding Monitor update: settlement-interval detection hardened across all 17 venues

Mikko Ohtamaa — Margin Syndicate / Trading Strategy · LinkedIn post

Why it matters: a perp paying -0.10% per settlement costs you 0.3%/day on an 8h cycle — and 1.2%/day on a 1h cycle. Same headline rate, 4x the real cost.

Most aggregators don't standardise for this!

If your tooling assumes 8h everywhere, your carry math is fiction on exactly the venues where the extreme rates live.

Two bugs were actively wrong in the UI:

Blofin — the venue's bulk spec was transiently flipping confirmed 1h contracts back to 8h and our writer chain trusted the spec over observed settlement history. Fixed by inverting the authority chain: settlement history > venue spec > adapter default, enforced across the detector, fanout poller, backfill RPC and drift monitor, with a job lock to stop concurrent writers racing.

KuCoin — the per-symbol adapter hard-coded 8h and ignored fundingRateGranularity from the contracts endpoint. Now wired to the bulk contracts cache, same pattern as Blofin.

Same pass closed latent risks: venues with no authoritative spec field (Bitunix, HTX, CoinEx, Crypto.com, WhiteBIT) now fall back to a detector-derived interval from settlement-timestamp medians — structurally, so no future adapter can silently default to 8h. Plus a rounding fix in OKX interval derivation.

If you trade funding, check what your data source assumes about settlement frequency. The answer is usually "8h" and the answer is usually wrong.
