Today, I tested another very interesting quantitative factor called the "Price-Volume Decoupling Reversal Factor" (I'll include the test charts below) The logic is actually quite intuitive: Under normal circumstances, there should be some kind of "synergistic relationship" between price and trading volume—rising prices accompanied by increased volume, falling prices accompanied by decreased volume, which is a typical manifestation of market consensus. But when this relationship breaks down in the short term, such as when prices rise but trading volume doesn't

expand synchronously, or when volume changes dramatically but price reacts sluggishly, it often indicates structural divergence within the market. The factor formula is as follows: $(-1 * \text{RANK}(\text{COVARIANCE}(\text{RANK}(\text{CLOSE}), \text{RANK}(\text{VOLUME}), 5)))$ Essentially, it's capturing the structural mismatch brought about by "price-volume synergy failure" in the market, and attempting to capture reversal profits in the process of this mismatch reverting to a normal relationship. Just two lines of source code can run a complete backtest—everyone can give it a try.
